Component tester in our oscilloscopes is altogether different from others. In addition to all Oscilloscope functions, the component tester provision can test all components passive and active, in circuit and out of circuit. ONLY OUR SCOPES CAN recognise NPN/PNP. Distinguish HIGH/LOW Gain, Distinguish AUDIO, R.F., SWITCHING transistors.

**MULTI FUNCTION OSCILLATOR**

- Pure Sine wave output.
- Amplitude settable with ease down to millivolts. X 1, X 1/10 and X 1/100 attenuated outputs available.
- No amplitude bounce when frequency varied.

Whatever your multimetering needs...

Motwane has its measure.

Have you ever thought of how dependent we are on electricity and what an indispensable instrument the multimeter is today? There is not an industry, Communication and Utility service, Defence force, or even a general technician that does not use one.

Much has been made of the merits of Digital Multimeters over that of Analog ones, but in truth both enjoy basic inherent advantages. It is simply a matter of the right application you must give your measurements the instrument they deserve.

The prime benefits of Digital Multimeters lie in their:

- Unambiguous readings—no slight operation
- Speed—readings in milliseconds
- Accuracy—non-offset operation
- Minimum circuit load and bonus features such as True RMS, Conductance measurements and Dioda testing—like the Motwane DM 450—the 4½ digital that stands tall with the best in the world, and our DM 351—the 3½ digital whose features other companies are still designing.

Yet there is no denying the innards of Analog meters when you need it. The trend in variations to be easily perceivable—readings in peaking and nulling. Wide dynamic resistance not limited by the number of display digits. Excellent immunity to voltage transients. Quick go-no-go checks. A totally plastic instrument—like the Motwane BX Mark III—the brand old man of Multimeters—experienced and confident, and the EX Mark I—the handheld bred with an eye on cost effectiveness and field operations. We are the only company in India and one of the few in the world, to offer you the best of both worlds—Digital and Analog. Motwane is the certain guarantee of Quality, that's exclusive, at a price that's not—from any measure.

Today BESTAVISION are in the news...

TOMORROW, THEY'LL BE MAKING HEADLINES

Improved standards of living, coupled with Doordarshan's vastly expanded transmission facilities have already generated a substantial increase in the demand for TVs.

With growing emphasis on modernisation in management and industry, the demand for computers is also going up at a rapid pace.

In view of the above factors, the 7th Five Year Plan envisages a spectacular 500% growth for the Electronics Industry. And the Government is extending massive support to make this growth possible.

Bestavision Electronics Ltd., are all set to cash in on the favourable opportunities offered by the electronics boom, by setting up a plant in NOIDA for manufacturing both computers and TVs.

Today, this Company is already well known for the vast range of televisions marketed by them. And now, people are talking about their ambitious plans for manufacturing televisions, VCRs, VCDs, Computers, Computer peripherals, microprocessor-based systems, and various other electronic items, in technical tie-up with the world-renowned IAP International of U.S.A.

With the vast experience of their dynamic Managing Director, Mr. A.C. Bajaj, and the technological expertise of their highly qualified team, the professionally managed Bestavision are heading fast for a lead in the field of electronics.

With all this in their favour, wouldn't it be surprising if BESTAVISION hit the headlines soon?

HIGHLIGHTS
- Existing profit-making Company.
- Professional management by persons having intensive experience and expertise in electronics.
- Technical tie-up with IAP International U.S.A., the renowned world leaders in the field of electronics.
- 80cc, 80l and wealth tax benefits.
- Extensive product range for the home, office and industry.
- No gestation period — assured dividend and excellent future prospects.
CMOS Technology RCA 1802 Microprocessor Based Microcomputer and Control Systems, for DEFENSE APPLICATIONS, FIELD DATA LOGGING, Electroplating Process Control and other Industrial Applications.

Extremely low power requirements of CMOS chip makes it most suitable for field applications and stand alone units.

- **CMOS** 8-bit Microprocessor RCA 1802 with 16 bit Multi function registers matrix of 16 x 16.
  - This extremely reliable and breakdown free Microprocessor has been built into the space shuttle satellites and other military devices.
- 1802 calls a sub-routine in 2.5 micro seconds (as against 8.5 microseconds of Z-80).
- Rapidly switchable program counter (faster than a Jump in Z-80).

- Requires 1.5 Bytes per executed instructions (as against 1.9 Bytes per instruction for Z-80).
- On 1802 one can generate powerful Pseudo Codes with the available page addressing.
- A complex and systematic Microprocessor with true built-in Direct Memory access.

Printed Circuit Board designing in our houseless.

Layout & Artwork in use on polyester film, Laid on art paper.

- Further making Artwork & Photography facilities.

- Turn around 7 days for Layout art and 14 days for generation orders.

- From the date we accept your order, urgent orders will be treated appropriately.

- Please ensure that the circuit diagram is complete and legible.

Circuit diagrams, Artwork Levelette etc., being proprietary item will be treated as confidential.

Clients outside Bombay will be serviced by post, whereas their artwork can be preserved with us. Layout, circuit diagrams and photographic material will be supplied on request.

Artworks can be collected from us at any time, as required.

PCB disregard rates are minimum charge being Rs. 100/pc.

- Double sided / PTH: Rs. 30/pc in (2 & 4 85/95 Gm)
- Single sided: Rs. 20/p in (4 85/95 Gm)
- Legend printing artwork: Rs. 15 per label.
- soldering artwork: Rs. 15 per label.
- Photography charges: Rs. 25 per label.
- A full description of the actual area of the PCB.

We can supply phenolic, glass epoxy and printed through boards.

- Designing, Drilling and Turning will be at extra costs.

We propose to set up a DEALER NETWORK for Hobby Kits. A provide after sales Technical Service. To achieve this, we are pleased to appoint Dealers from the hobbyist community. Retailers, colleges, and hobbyists all over India. Retailers Dealer are also invited to participate in our NETWORK.

We have identified more than 500 Projects in kit form, complete with hardware, chips, electronic parts, component layout, acrylic boxes, and other necessary materials. We are constantly working on new ideas, and the kits are specially designed for the hobbyist. All kits include an assembly instruction manual, necessary parts, and the hobbyist. We are constantly working on new ideas, and the kits are specially designed for the hobbyist. All kits include an assembly instruction manual, necessary parts, and the hobbyist.

For further details of dealership approval, project list, and Technical assistance regarding circuit problems, contact us at the above address.

We propose to conduct a small seminar for all prospective Dealers so that they may qualify for the kit on their own. The seminar will be conducted at the above address.

We can convert your circuits into kit form at a very reasonable price. We have the facility for generating Layout & Artwork for PCBs.

This mixer is not designed for the occasional party, where one slide control per channel will suffice. Rather, it is intended for the serious electrophonics enthusiast. And quite naturally, therefore, it has all the facilities such users have come to expect.

Professional mixers are expected to meet a long list of special requirements: balanced and unbalanced inputs and outputs; independent control of each channel for driving special effects equipment and monitors; automatic setting of input sensitivity to match the signal level; multiple tone controls per channel; and many more. No wonder that such mixers are, to put it mildly, pretty expensive. It is, however, possible, to build one of comparable quality at much lower cost, as described in the following pages.

Modular construction

The mixer is constructed from four modules. A fifth module provides the power for the entire mixer. The mono input unit is almost certainly the most often used module. Its input sensitivity is adjustable between 0 dB and +60 dB. This enables all sorts of mono signal sources, from microphone to keyboard, to be connected to this module. The unit is provided with a three-way tone control; a peak indicator for possible overloads; a monitor; a multi-track or PFL (pre-fade listening) control; and
a panorama control. Balanced inputs are standard, but any of these can be made unbalanced by connecting one of its terminals to earth.

The stereo input unit is intended for use with a variety of signal sources. Its input can be switched between MD (variable-reluctance pickup), AUX (high-level stereo), and LINE (mono). The latter position is for use in the event the mono module is not available. The balance control functions as a panorama control when the input is switched to LINE.

The headphone-monitor module contains a stereo headphone amplifier via which each module may be monitored. Unlike other modules, this unit is provided with a parametric equalizer instead of a three-way control. This is a very useful facility, because it enables any tendency to acoustic feedback between the microphone and monitor loudspeaker to be suppressed effectively. The main controls and output terminals of the special effects channel are also fitted on this module.

The most important unit is the output module. Apart from the main tone control and other refinements, it has a stereo LED VU (volume unit) meter. The output is available as a balanced or as an unbalanced signal.

Power supply

Since any equipment is only as good as its power supply, all the supply lines in the present mixer are stabilized twice: once in the power unit and once in the relevant module.

Apart from its mains transformer and on/off switch, the power supply unit shown in Fig. 2 is contained on a separate printed-circuit board. It is suitable for the supply of up to eighteen modules.

Regulators IC1 and IC2 hold the supply voltage, preset with the aid of R5 and R6, at ±18 V. Transistors T1 and T2 and associated RC networks ensure a sufficiently slow rise of the supply voltage to prevent loudspeaker clicks when the mains is switched on. Resistor R4 is a voltage-dependent resistor that suppresses noise present on the mains.

Switch S1 enables the mains earth to be isolated from the case earth, which may be necessary in certain theatres. If S1 is open, and something goes wrong, neon lamp L1 breaks down, and the mains fuse blows.

The values of resistors R4 and R5 can be ascertained precisely for any individual power unit by replacing them by two 5 k preset potentiometers. Adjust these presets until the output of the relevant regulator is 18.1 V. Switch off, remove the presets, and carefully measure their values with an ohmmeter. Fixed resistors with values so found should then be soldered in the R5 and R6 positions (this may, of course, entail making up a parallel combination to obtain the correct value). Check that the output voltages of the regulators are still ±18 V.

**MIC-LINE module**

Although the number of presets may give the impression of complexity, the circuit in Fig. 3 shows that this would be misleading. Operational amplifiers A1, A2, and A3 form an instrument amplifier that provides properly balanced inputs.

The sensitivity of the microphone input is about 20 dB higher than that of the line input.
To keep the overall noise level down, $A_1$ and $A_2$ are low-noise types, while $R_1$ to $R_9$ incl. are high-stability (1%) metal film resistors.

Gain control $P_1$, which enables setting the gain between 20 dB and 60 dB, must be a high-quality type, because it is located in a noise- and scratch-sensitive position. The peak indicator is formed by transistors $T_1$ and $T_2$. The threshold of operation is fixed at 9 $V_{pp}$ or 3 $V_{rms}$ by voltage divider $R_1$ to $R_9$. These levels correspond to a microphone input of 3 mV $rms$ at maximum amplification. Reservoir capacitor $C_1$ ensures that short-duration overloads are also clearly indicated.

Coupling capacitor $C_2$ prevents any DC reaching the potentiometers and connects the amplified input to the three-way active $(A_1)$ tone control. Effect control $P_2$, of course, precedes the tone control stage.

Potentiometer $P_3$ sets the wanted monitor output level.

Stereo slide potentiometer $P_4$ is the fade control.

Since a signal to drive a multi-track recorder is also required, slide control $P_5$—the fader—is a stereo type to prevent any feedback between the stereo channel and the multi-track outputs. An alternative to this arrangement is to provide each channel with a PFL (pre-fade listening) facility; $C_3$-$R_9$ can then be omitted. $P_4$ can be a single track control, and $S_1$ and $S_2$ are fitted externally.

### Stereo input module

The stereo input module—see Fig. 2—has no balanced input; instead, it is provided with an equalizing pre-amplifier, formed by $A_1$ and $A_2$ $(A_1'A_2')$, for use with variable-reluctance pick-ups.

Input selection is effected by $S_1$: position 1 is for variable-reluctance pick-ups; position 2 for high-level inputs, such as from tape recorders; and position 3 for mono signals. Position 3 is for use when the MIC-LINE module is not available, or, for instance, when more equipment is to be connected than was originally foreseen. Note, however, that only line signal sources can be connected: not microphones. The (unbalanced) signal is then taken from the right-hand AUX input, and amplified in $A_2$ and $A_2'$ by a factor 3. Stereo potentiometer $P_1$ provides a monophonic effects signal, but is arranged such that its input and output resistance are equal, whatever the position of the wipers.

The active tone control is followed by the controls for the monitor output $(P_3)$, the channel output $(P_4)$, and the balance $(P_5)$. With $S_1$ in position 3 (LINE), the balance control functions as panorama control. The pre-fade listening facility is constructed with (external) components $R_9$, $R_{10}$, and $S_3$.

A multi-track output is not necessary in this module, because the unit is normally fed from a multi-track tape machine. If the MD input is not required, the operation of $A_1$ $(A_1')$ can be made linear by omitting $C_2$ and $C_3$ $(C_1'$ and $C_2')$, and replacing $R_9$ and $R_9$ $(R_3'$ and $R_3')$ by $R_x$ $(R_x')$. The value of the new resistor may be calculated from

$$R_x = R_x(\alpha - 1)$$

where $\alpha$ is the amplification of the amplifier. If the amplification is large, $R_x = R_x'$. 

---

Fig 5. The printed-circuit board for the MIC-LINE module
Capacitor $C_i$ may be adapted to match the output impedance of the tape machine used.

**Construction**

Before buying any new components, it is wise to determine how many modules are required.

Prepare the printed-circuit boards shown in Fig. 6, Fig. 8, and Fig. 9; note that the board in Fig. 8 consists of two parts, which must be separated before any components are fitted.

The dimensions of the front panels are given in Fig. 10: 10a is that for the MIC-LINE module; 10b that for the stereo module; and 10c that for the power supply. The overall length will, of course, depend on the cases used. The prototype was built in one aluminum case with compartments for the various modules. The construction of this will be described in next month's issue.

In the mean time, the completed modules may be tested by connecting their outputs to the TUNER or...
Fig 8 The printed circuit board for the stereo module consists of two parts, which must be cut apart before any components are fitted.

Parts list

Resistors
R₁, R₂, R₃, R₄, R₅ = 100 k*  
R₆, R₇, R₈ = 1 k  
R₉ = 220 k  
R₁₀ = 1 M  
R₁₁ = 47 k  
R₁₂ = 10 k  
R₁₃ = 10 k  
R₁₄ = 68 k  
R₁₅ = 145 k  
R₁₆ = 1 M

P₁ = 25 k linear stereo potentiometer  
P₂ = 100 k linear stereo potentiometer  
P₃ = 25 k logarithmic stereo potentiometer  
P₄ = 10 k logarithmic stereo potentiometer  
P₅ = 10 k linear stereo potentiometer

* 1% metal film type
+ with 4 mm spindle for PCB mounting

Capacitors
Polypropylene or polycarbonate unless otherwise indicated:
C₁, C₂ = 100 n  
C₃, C₄ = 220 n  
C₅ = 100 µF at 50 V  
C₆ = 470 n  
C₇ = 22 n  
C₈ = 10 n  
C₉ = 100 p  
C₁₀ = 100 µF at 16 V  
C₁₁ = 22 µF at 6 V

L
AUX input of a stereo power amplifier, and injecting a suitable signal into the various module inputs. The correct operation of all potentiometer controls can then be checked.

Part 2 of the Portable Mixer will appear in the next month's issue.

Semiconductors:
- D₁, D₂ = 1N4148
- D₃ = LED, red
- T₁, T₂ = BC557B
- IC₁ = NE5532 or LM308
- IC₂, IC₃ = TL072
- IC₄ = XR4195 (see fig. 9)

Miscellaneous:
- S₁ = 3 pole 3 position rotary switch
- S₂ = DPDT 2 mm switch
- 3.5 mm insulated stereo chasis socket (6.3 mm dia. mounting hole)
- XLR Cannon type 3-pin chasis socket
- 13-pole PCB-type connector to DIN41617
- Knobs for potentiometers as required
- Front panel foil 65012-2*
- PCB Type 65012-2*  
  * available through our Readers Service (see p. 82)

Fig. 9 This illustrates how the boards can be screwed together.

Fig. 10. Drilling plans for the front panels: (a) the MIC-LINE module, (b) the stereo module, and (c) the power unit.
Many high-resolution graphics images may be considerably embellished by highlighting and enlivening effects such as controlled colour flashing and inversion, since the degree of screen animation seems to be proportional to the interest viewers take in watching the image.

**FLASHING COLOURS**

The proposed circuit has been designed for insertion between the digital RGB(I) outputs of the Elektor high-resolution colour system and a RGB(I) monitor; see *Elektor India* issues from October 1985 onward. The colour inversion and flashing effects are entirely under software control (BASIC); they are easily brought about by writing appropriate data to a specific memory location, as will be explained further in this article. Since the proposed design of the flash/invert extension is fairly universal, other graphics colour systems may also incorporate it, provided the necessary control signals are available.

**Colour inversion**

One of the fundamental operations in Boolean algebra is referred to as the *exclusive-OR (EXOR)* bit manipulation method, which is a means for controlling the digital polarity (inverted/non-inverted) of an operand A when this is applied to either one input of an EXOR type logic gate, the other input being driven by a logic level (0 or 1) PROG. Depending on the logic level assigned to PROG, operand A will appear either in the non-inverted form \( B = A; \) PROG = 0, or the inverted form \( B = \overline{A}; \) PROG = 1 at the EXOR gate output; see the diagram opposite this text illustrating the logic function of this programmable inverter gate.

In the present add-on circuit, gates N1 to N20 receive the RGBI signals and a common control level COLOR which is obtained by latching the Da databit from the host processor bus during a memory write operation to I/O map location XX67 — see Fig. 1.

![Diagram](image-url)

**Fig. 1.** A few SSI gates, a dual counter, a latch, and two diodes constitute a programmable flash/invert add-on circuit for the high-resolution graphics card. All signals at the left of the figure come from the existing main and colour extension board. Application of HCTI type ICs is preferred for ICs and ICs, although standard LS equivalent types will also do.
Thus, by setting and resetting this bit at the indicated memory location, the user is in control of simultaneous colour inversion of all picture elements. Since there happened to be an EXNOR gate left over in IC3, this was put to good use as an additional I output along with I.

### Flashing colours

The colour flash circuitry is a bit more complicated than the combination of gates to effect colour inversion since, as opposed to the overall effect of the latter, the flash circuit section operates specific to any of the colours red, green, or blue. To start with, some slow, periodic switching signal is required to determine the flash rate. The present design enables software selection of two flash rates, fast or slow, as selected by the logic level of D1 written to XX67. In order to ensure the necessary fixed phase relationship between picture scan and flash pulse, the vertical blanking pulse (VB) is applied to the CXI input of a dual 4-bit counter Type 74L5393. The outputs QA and QB of the second counter section in this IC have been selected to supply two flash frequency rates to selection gate network N2, N3, N4, and the two diodes in OR configuration. Fast or slow flashing is now under control of the F/S signal; in other words, D1 at XX67. Note that proper operation of the diode OR simulator may only be achieved with the use of HCT3 types for IC1 and IC6 which must feature good high and low level definition to compensate for the inevitable voltage drop across the silicon diodes. However, where these new types are not yet available, the use of 74LS equivalent types may be resorted to.

The function of the other logic gates in the circuit is best elucidated by starting at the output side of the proposed design, establishing, for instance, the order in which the red (R) signal is processed. When pin 2 of N4 is permanently at high logic level, the red bit is simply passed by this gate; if, however, the logic level at this pin is arranged to toggle along with the flash signal, the red output bit will also flash, whether or not inverted by N7. Gate N8 functions as a programmable switch to pass or block the flash signal to N4; if the user sets RF (red flash, D1 at XX67), red flashes. It will be readily understood that the other colour bits may also flash if their F bit has been set with an appropriate instruction.

### Colour selection

To select between flashing the eight bright or the eight pale colour shades, the I (intensity) bit is applied to gates N6, N2, and N3 together with three intensity select bits RI, GI, and BI. If we take red once more as an example, it will be seen that AND gate N4 will only pass the flash signal if its pin 1 is at logic high level, that is to say, only if the user-programmed level of the RI bit is the same as that of the I bit. Thus, the user may have bright red flash by setting RI (i.e. logic high); whereas pale red flashes with RI low, since the I bit is also low in this condition.

### Hardware and software

The flash/invert circuit had best be put together on a small piece of vero board, and construction should present no problems to those who have already been successful in putting the Elektor graphics system together. The databus connections to the octal latch are made with eight short lengths of wire to points 6...13 on the colour extension card; the XX67 signal is available at pin 9 of IC1 also on this card (see Elektor India, March 1986 issue). As far as the VB signal, this may be taken from pin 16 of the GDP chip, wired to an unused pin on the 64-way DIN connector (for example pin 8c), and put onto the bus for use in the flash/invert circuit. Finally, do not forget to fit every IC with a decoupling capacitor and avoid long wire runs, which may result in picture degradation due to cross-talk effects.

Since the video interpreter for the high resolution graphics system does not support programming the present add-on board, the user must rely on his BASIC interpreter to transfer the necessary codes. Table I summaries the bit functions and gives examples of how a specific effect may be obtained by setting or resetting bits at XX67. Note that the user must first calculate the decimal equivalent of this output address for his configuration in case the BASIC interpreter does not allow the use of hexadecimal address notation in a POKE instruction.

In conclusion of this article, some examples of POKEs to effect interesting effects on the screen:

- POKE XX67,8 inverts all colours;
- POKE XX67,16 causes the pale red pixels to flash slowly, and POKE XX67,144 flashes the bright red ones at double speed.

POKE XX67,272 gives a fast flash of bright blue and pale red.

---

**Table 1.** Every bit written (POKEd) to XX67hex specifies a function in the flash/invert extension; the examples listed in this table should illustrate some of the possible programming configurations with their resultant effects on the RGBI monitor.
A loudspeaker presents a complex load to the output amplifier and the cross-over network. This load can be measured and any deviation from the nominal impedance corrected. In this manner a multi-way loudspeaker system with a passive cross-over network can be made to function optimally.
Dynamic impedance

A drive unit may be represented by an electrical circuit containing resistance, capacitance, and inductance. Its impedance may, therefore, be inductive, capacitive, or resistive, depending on the frequency of operation. Moreover, the impedance is affected, to some extent, by the type and dimensions of the enclosure in which the drive unit is housed. Figure 1 shows the dynamic impedance of a 17 cm bass unit measured over the frequency range of 20 Hz to 20 kHz. This curve is characterized by the peak around 75 Hz and the slowly rising impedance with frequency. The peak is caused by the resonance frequency of the equivalent circuit, while the rising with frequency results from the self-inductance of the voice coil. As the crossover network has been designed for operation into a constant-value ohmic load, the performance of the system will be adversely affected by this varying impedance.

Equivalent circuit

A (simplified) equivalent circuit of a typical drive unit is shown in Fig. 2. The voice coil has a resistance, $R_e$, which determines the minimum impedance of the drive unit. From the curve in Fig. 1 it is clear that for the drive unit used here $R_e = 5.5$ ohms. The inductance of the voice coil is represented by $L_e$. The parallel circuit $L_e C_{o} R_e$ causes exactly the same peak as the drive unit proper. Note that it is in series with the series combination of $R_e$ and $L_i$.

Impedance calculations

A dynamic impedance characteristic, such as that in Fig. 1, can be determined with the simple setup of Fig. 3. If the resistance $R$ is large compared with the nominal loud-
speaker impedance, the AF signal source functions as a perfect current source. If, for instance, $R=3\,k\Omega$, and the output of the signal source is set at 3.3 V rms, the current through the loudspeaker coil is 1 mA. Each millivolt drop across the loudspeaker, therefore, represents 1 ohm. It is clear that the true RMS voltmeter should be a sensitive type. The impedance presented by the loudspeaker can now be measured over a range of frequencies, and the curve plotted from the values measured. If it is, of course, essential that the drive unit is housed in its normal enclosure to ensure that the true impedances are measured.

The voice coil resistance, $R_v$, may be measured with an accurate ohmmeter, or with the set-up of Fig. 3. The latter is not too accurate, but it will do. In this case, the minimum impedance over the frequency range is ascertained.

Next, ascertain the impedance, $Z_o$, at the resonant frequency, $f_0$. The true impedance, $Z$, is

$$Z = Z_o - R_v$$  \hspace{1cm} (1)

Subsequently, calculate the impedance, $Z_3$, at the $-3\,dB$ points from

$$Z_3 = R_o + Z\sqrt{2}$$  \hspace{1cm} (2)

Measure at which frequencies above and below $f_0$, to and $f_o$ respectively, the impedance has the value $Z_3$. The bandwidth, $B\omega$, of the resonance peak is calculated from

$$B\omega = f_o - f_b$$  \hspace{1cm} (3)

Values at the equivalent circuit components can now be calculated from the following.

$$L_o = B\omega Z/2f_0$$  \hspace{1cm} (4)

$$C_o = 1/2\pi B\omega$$  \hspace{1cm} (5)

$$R_o = Z$$  \hspace{1cm} (6)

For bass speakers, measure at which frequency, $f_1$, the impedance is equal to $2R_v$. Then,

$$L_o = \sqrt{3}R_v Z/2f_1$$  \hspace{1cm} (7)

For middle and high frequency speakers, measure at which frequency, $f_2$, the impedance is equal to $\sqrt{2}R_v$. Then,

$$L_o = R_v Z/2f_2$$  \hspace{1cm} (8)

**Fig. 3** Typical set-up for measuring loudspeaker impedance over a range of frequencies.

**Fig. 4** An RC network across the loudspeaker compensates for the rise in impedance with frequency.

**Fig. 5** The resonance peak of a loudspeaker may be negated with a suitable LCR network across the unit.

\[ R_b = R_c + R_t^2/R_c \]  \hspace{1cm} (13)

These correcting networks ensure that the passive cross-over filter is terminated into a constant-value impedance.

\[ R_c = R_v \]  \hspace{1cm} (9)

\[ C_o = L_o R_v R_b \]  \hspace{1cm} (10)

Note that the minimum impedance of the loudspeaker remains equal to $R_v$.

Correcting the resonance peak is normally not necessary, because it usually lies well outside the pass band of the cross-over network. None the less, where it is felt necessary, it can be done with the aid of the circuit in Fig. 5. Here,

\[ L_b = L_o R_t R_b \]  \hspace{1cm} (11)

\[ C_b = C_o R_t R_b \]  \hspace{1cm} (12)
COMPUTERS AND HEALTH CARE

by Helena Buswell

When a 38 year old Scottish housewife made an appointment to visit her doctor at the local health centre, she was unaware of the role that computers were about to play in her life.

Mrs Ann Robertson (not her real name) had stomach pains, and, like most people, was nervous when she tried to describe her condition.

Dr Michael Ryan had before him a summary listing her patient's details produced by the health centre's computer ready for Mrs Robertson's visit. He could see at a glance her age, number of children, occupation, height, weight, blood pressure, previous and current health problems, and other demographic data relevant to her general health.

Almost all of the 5.6 million population is registered with one of about 50,000 general practitioners (GPs), contracted to work within the National Health Service (NHS). Each GP has a list of several thousand people, and for each and every one he has case notes — most going back to that person's birth. At health centres like Howden, near Livingston in central Scotland, these details have been transferred to new computer systems, which produce a summary sheet ready for each patient's consultation.

Further tests

In Mrs Robertson's case, Dr Ryan decided to send her to the area hospital — Bangour General Hospital — for further tests. Her appointment there had already been computer generated, and, when she arrived, more details were entered into the computer system by the receptionist. As Mrs Robertson had been a patient at the hospital some years before, the computer automatically alerted the hospital staff, and her earlier case notes were produced.

Bangour uses the de Dombal system for diagnosing abdominal conditions. Developed by Tim de Dombal, a consultant surgeon at Leeds General Hospital, this computer-based diagnostic system assesses the chances of different causes of acute abdominal pain with a very high degree of accuracy. The system is now used in many British hospitals, and, with fewer unnecessary exploratory operations on the abdomen, more patients are sent home from casualty wards and both lives and money are saved.

The system is also used in submarines of both the US Navy and the Royal Navy. Dr Ryan says: "In these sorts of conditions, with long periods at sea, acute abdominal complaints are the most critical to diagnose correctly. After all, apart from heart attacks, they are the most likely to kill you!"

A comparable system in use at Glasgow has a dyspepsia program that obtains data on symptoms by directly interviewing the patient. Where direct computer interviewing is also used, the patient is often more relaxed and forthcoming, talking directly to a machine, rather than to another person. The de Dombal interview has already been translated into Swedish and Dutch, and is being tested in other clinics here and overseas.

Possible appendicitis

Mrs Robertson, however, was asked a series of structured questions by the hospital doctor, and her answers keyed into the computer. The computer's diagnosis showed a 99 per cent chance of appendicitis, with lesser chances of constipation or gynaecological abnormalities.

Admitted to hospital, Mrs Robertson's subsequent operation and stay were logged from start to finish on the hospital's computer. Her files, both at the health centre and Bangour, were updated. Howden Health Centre is one of 50 to have recently installed computer systems.

Management information

The NHS is introducing new management information systems in the next two to three years, and their success will rely heavily on the use of computers. However, computers are not new to the health service. Some were installed nearly 20 years ago, and with this wealth of experience, the NHS is now marketing a range of software in other countries. Milton Keynes General Hospital is typical of those...
Wider health context

Although computerized bed management has been developed to facilitate the smooth running of hospitals, the accumulated data can provide vital information in a wider health context. At Milton Keynes, a potential minor epidemic was averted after a patient, who had entered hospital for routine treatment and a two week stay, was discovered to have active tuberculosis. From computer data, all his contacts from several wards — staff, patients (most of whom had already been discharged), and even visitors — were located in less than 24 hours. A special clinic was set up for screening and immunization the same day. Payroll systems were among the first computer applications introduced by British health authorities. The West Midlands Regional Health Authority uses OMR (Optical Mark Reading) forms and readers to process a complicated payroll for 102,000 people working in a widespread area. In a further complication, about $2 per cent are monthly salaried, with the rest being paid weekly. "People fail to realize that every sort of trade and profession — from surgeon to carpenter — is employed by the NHS," says computer operations manager Peter Owen, "We have one of the most complex payroll structures in the country. At least once a month some 200,000 OMR documents are being processed." The East Anglia Regional Health Authority covers Cambridgeshire, Norfolk, and Suffolk, and has a population of two million. The eight major hospitals, and many of the smaller ones, have computer systems dealing with administration, in-patients and out-patients, radiology, and pathology. Pathology statistics help to analyse the incidence of medical conditions, providing valuable leads to links between such parameters as occupations, social conditions, and the occurrence of illness. As with all regional authorities, East Anglia writes its own software. A recently developed catering program at Peterborough General Hospital has simplified patient menu orders, and has drastically cut costs. Around the area's health community centres, all child health immunization programmes are also computerized.

International Computers Ltd (ICL) has emerged as one of the leading suppliers of computer equipment to the NHS. Formed in 1968, ICL operates in over 70 countries and employs 21,000 people worldwide. It has collaborative agreements with Fujitsu of Japan; PERQ Systems of the United States of America, and Mitel of Canada, and also has a joint research institute in Munich with Bull of France and Siemens of West Germany.

Patient administration

ICL has recently formed the ICL Health Systems Business Unit. It includes the 100 strong team that has been working on the ICL Patient Administration System already ordered by about ten health authorities. The company also runs seminars for NHS personnel and ICL user groups.

An idea of the scale of ICL’s health computer systems, and of the phenomenal growth of NHS computerization, is evident in just a short selection of recent installations.

An ICL supplies information system being installed for the Grampian Health Board in Scotland will handle 6,500 stock items, ranging from staff uniforms and cleaning material to surgical needles and sutures. The Brighton Health Authority is installing two new networks for district information, replacement, and upgrading older hardware. Brighton will also be one of the first districts to install an obstetrics software package developed at St Mary's Hospital in London, where the Princess of Wales had her children. Obstetrics computer systems have helped reduce perinatal death rates.

Tender letting control systems have been installed by seven health authorities to help with the administration of the tendering process, including the monitoring of successful contractors.

Real-time systems

A new real-time patient administration system is being used by the West Glamorgan and Gwynedd health authorities. Supplies information systems have been installed by all the districts under the southwest London Regional Health Authority, and six districts of the Oxford Health Authority.

Apart from systems based on orthodox computer hardware, British scientists have developed advanced computer based technology for the specialized diagnosis and treatment of a range of illnesses. The National Hospital for Nervous Diseases in London, for example, is to have a prototype expert system called BRAINS designed to give powerful aid in the analysis of brain scans. The main goals of a team from University College, London, Leicester Polytechnic, and the hospital were to give the radiologist a tool for fast and efficient study of the scan image, and to reduce unnecessary scans. The team decided to
make use of the statistical methods that had grown up in epidemiology in the last 25 years. A statistical database of 900 scans has been entered into the system by Mr. du Boulay, the team's radiologist. The database took five years to collect, covers 22 different forms of cerebral disease, and can be extended. The system allows less experienced radiologists to access sample scans of diseases and compare them with the scan of the patient being examined. To get advice from the system, the radiologist is required to describe the position and appearance of damaged tissue, and indicate the presence or absence of other signs. Based on this information, the system gives a shortestlist of disease probabilities, and indicates which symptom leads to its prediction.

ELECTRONICS AND TEMPERATURE CONTROL

by Vic Wyman

Temperature control is often the key to efficient and economic industrial production. In many process plants, for example, the temperature may need to be held within narrow bounds if the process is to be a success. And the close control of the temperature of production processes and of factory environments can often save a large chunk from a company's annual energy bill.

A growing number of control equipment suppliers recognize that simply knowing a temperature is of little use. What is needed is the ability to monitor how temperature is changing and adjust it accordingly. These demands are being increasingly satisfied as electronics expands the options of equipment designers and allows low cost solutions to past problems.

Microprocessor based

A good example of the great flexibility available with the latest temperature controllers is the microprocessor based digital unit from Control & Readout®, designated the 451. The general purpose 451 is aimed particularly at machine makers and users in the food, plastics, oven and furnace industries, and accepts a range of inputs. But as well as being a proportional, integral or derivative (PID), three term or on/off control unit with a range of common features, the 451 is easily reconfigured to change the basic functions. The measurement range, control algorithm and limit mode, as well as PID terms, output cycle time and limit setting, can be changed as often as wanted. Because of this, any 451 can serve as the spare for other units, cutting the number of controllers held in stock and minimizing the cash tied up in spares. The 451 can take inputs from K, J and S sensors over the respective temperature ranges 50 to 1200 °C, 60 to 1000 °C, and 60 to 1600 °C, as well as from Pt100 sensors over −200 to + 400 °C and 4 to 20 mA, 10 to 50 mV or zero to 20 mA, 0 to 50 mV signals. The controller works on supplies of 115/230 V at 50/60 Hz.

Hidden button

For commissioning, an internal security switch is actuated and a hidden button on the front panel operated together with the normal controls. This allows the 451 to be matched to the process needs. Any reconfiguration requires entry of a special code after the actuation of an internal security switch. As an example of how input and output control functions can be altered, the unit could be changed from thermocouple input with on/off control to a resistance thermometer sensing instrument with PID control. A non-volatile memory retains the configuration for more than ten years, even without power.

For slow and controlled heating of large structures, the 451 has a soft start or controlled ramp function, with a digitally set rate of 0.1 to 50 °C/minute. An automatic manual option also allows such processes as mixing to be started manually and then switched to automatic control. The device has 5 A relay or logic outputs.

Self-tuning adjustment

Another digital indicating temperature controller is the 810 unit, which, like the manufacturer, Eurotherm®, claims, has carved out a niche for itself in industry only a short while after its introduction. The device was invented by the Design Council in 1984. To expand the market further, the company has introduced a self-tuning control adjustment aimed mainly at the plastics extrusion and continuous furnace markets. The new feature is intended to cut out long, involved manual adjustment. The 810 is a three term, microprocessor based instrument with a high degree of control accuracy and easy front panel adjustment of all 15 main parameters. It features a new, self-tuning algorithm for such equipment as extruder barrel and die zones, where there is a maximum rate of temperature change under full power of about one unit per second, requiring only 300 bytes of code space. The three easily set operating modes provide self-tuning on startup as long as the measured value is well below the desired set point, and self-tuning at set point if the loop is over-damped or under-damped. In the third mode, self-tuning can be initiated manually during operation.

There is a high or deviation alarm and three set-point and alarm ranges from zero to 500 °C, zero to 1000 °C, and zero to 1500 °C. The operator can override all the parameters available from the 810's scroll push buttons.

Set-point changed with time

The flexibility of the latest control equipment is illustrated by the possible uses claimed by Gulton® for its West 2050 programmable controller. The PID, microprocessor based unit is said to be suitable for the heat treatment of metals, kiln control, environmental chambers and cabinets, food and chemical processing, resin manufacture, textile dyeing and autoclaves, as well as other uses where set point must be...
The 2050, from the Gulton group's control and instrumentation division, is based on the established West Opus 70 temperature and process controller. It has the same mechanical construction and is in a metal case with splash-proof and dust-proof membrane front panels. The programmer controls a measured value through a set-point profile which can change with time through up to four stages, each with a ramp and a dwell segment adjustable up to 99 hours 59 minutes. Rate or time programming can also be adopted for the ramps. The 2050 can handle thermocouple, resistance thermometer, direct current linear, and voltage and current inputs. Output forms include relay, logic for solid state relay, direct current linear, voltage and current, thyristor pulse, and valve motor drive.

**Integral lock-out**

The manufacturer claims a 0.25% accuracy and the PID control has an integral lock-out. Typically, control parameters can be retained without power for five years, according to Gulton. The 2050’s optional extras include on RS422 serial interface, a digital (event) output, a remote programme start, and guaranteed soak times. Preliminary trials of FGH Controls’® furnace temperature controller, known as the thermal head ratio system, suggest typical fuel cost savings of 15 per cent. Aimed at such sectors as the aluminum industry, with medium sized and large furnaces, the system is claimed to improve the efficiency of heat treatment and to be simply controlled by non-specialist workers. Present control methods for furnace temperatures typically involve regulating the furnace atmosphere and letting the load warm to this temperature, or controlling the load at a chosen temperature and probably suffering from high atmosphere temperatures and high load skin temperatures.

**Thermocouples**

To eliminate the need for this wasteful system, FGH has come up with a two instrument and two thermocouple design. The thermocouples monitor load and atmosphere temperatures. One instrument compares the load temperature with a load set-point and generates a further set-point, which is led to the second instrument. The second set-point is compared with measured atmosphere temperature which it maintains. To avoid dangerously high atmosphere temperatures, the user can include a further set-point if the atmosphere controller instrument, operating as an upper clamp. A range of control components can be coupled to the system. FGH can also supply suitable thermocouples, and up to three can be used to sense load temperature. In this case, an additional control unit selects the highest temperature and switches this through to the ratio system.

A similar set of three thermocouples can be used for atmosphere temperature sensing.

**Factory heating**

Temperature control can also be applied profitably to the heating system of a factory or other plant. A recent addition to the energy management equipment made by Geni® is the microprocessor based 6202 temperature controller. This unit, which is easy to program with a 25 button keypad, can be used as a stand-alone energy management device or can form part of a more comprehensive control system. It is suitable for both existing and new heating installations. The 6202 can control up to eight zones, three boilers, a main system pump, a hot water circuit and alarms, with up to 14 digital outputs. The unit accepts signals from up to 24 dedicated analogue inputs. Geni sees as a particular advantage the ability of the 6202 to control energy use in any of three ways. The first, a pulsed power mode, links a zone direct to a boiler and pump operation. By monitoring outside and zone temperatures, the unit calculates the input power each zone needs to maintain the desired space temperature. By monitoring the system flow temperature, the controller also determines the period the zone valve needs to be pulsed open.

**Three way valve**

The modulating or valve mode calls for each zone to be controlled by a three way valve and zone circuit pump, with a corresponding zone flow temperature sensor. The valve is modulated in line with the outside and space temperatures. The third mode, designated on/off, is for a wide range of energy consuming plant such as oil and gas fired air heaters, electric heaters, lighting, and pumps. Independent zone operation allows time and temperature or time-override control. The 6202 can also be programmed with 99 consecutive shutdowns up to six days in advance, and there is a back-up battery to retain programs for up to 72 hours. The user can also select parameters to be coupled to alarm outputs, and an RS232/422 interface can be used to connect the unit to remote computer equipment.

---

The 6202 energy management unit from Geni can produce major cost savings when applied to factory temperature control.

Automatic slide changers are extremely useful when a recorded commentary is used to accompany a programme of slides. Most auto slide changers make use of a control signal. This may be a high frequency low level signal, recorded on the same track as the commentary, which is unobtrusive but which may be extracted for control purposes by a filter. Alternatively, an audio tone may be recorded on a parallel track.

The slide changer described here uses neither of these methods but senses the drop in signal level of the commentary when the commentator stops speaking for more than one second.
Figure 1 shows the simple circuit of the auto slide changer. In the absence of an audio signal at the input T1 and T2 are cut off. When a signal exceeding a predetermined level (set by P1) appears at the input then T1 will conduct on the positive peaks of the signal. The output from the emitter of T2 is integrated by C2 and T2. The collector voltage of T2 will be below the negative-going threshold of Schmitt trigger N1, so the output of N1 will be high. The output of N2 will go low and pull down the input of N2 via C3. The output of N2 will go high, turning on T3 and energising the relay. The relay contacts are connected to the remote change jack of the slide projector, so the slide will change. C3 will charge via R3 until the positive-going threshold of N2 is exceeded, when the output of N2 will go low ready for the sequence to repeat, and the relay will drop out. Diode D1 protects T1 against the back e.m.f. generated by the relay coil. P1 provides a preset bias on the base of T1 and thus determines the threshold voltage at which T1 starts to conduct. By suitable adjustment of P1 it is possible to have background music underlying the commentary at a low level. P1 is adjusted so that T1 is not turned on with background music only present, but will turn on during the much louder speech passages.

Figure 2 shows a typical setup for preparing a slide commentary. Recorded music and speech are mixed together and recorded onto tape. The slide changer is placed at the output of the mixer to check that the slide change does take place during pauses.
During the slide show, the slide changer is connected to the line output of the cassette recorder (figure 3), or some other point in the system where the signal level fed to it is unaffected by volume or tone controls, since once the changer has been set up the signal level must not be altered.

To set up the slide changer during recording, potentiometers P1 and P2 should first be set to their mid-position. P1 is then adjusted until the slide change will occur when a pause of about one second occurs in the commentary. P2 calibrates meter M1 to provide an indication of the threshold level. P2 should be adjusted so that M1 reads about a quarter scale when P1 is correctly set.

Figure 4. Printed circuit board and component layout for the auto slide changer (EPS 9743).

If the record and replay levels of the tape deck are correctly matched then no adjustment will be required when playing back the commentary. However, if the playback level is different from the record level then it may be necessary to adjust P1 to set the correct threshold level for playback.

A p.c. board and component layout for the slide changer are shown in figure 4. The unit requires a supply of 5 V at 18 mA (excluding the relay) which can easily be supplied by a simple zener stabiliser. A separate supply pin is provided for the relay, so that if a 5 V-6 V type is not available some other voltage can be used, possibly derived from the unregulated input to the power supply.

### Parts List

**Resistors:**
- R1 = 150 k
- R2 = 27 k
- R3 = 4k7
- R4 = 1 k
- P1 = 1 M preset
- P2 = 1 k preset

**Capacitors:**
- C1 = 47 n
- C2 = 4μF/10 V
- C3 = 220 μ/10 V

**Semiconductors:**
- T1, T2 = BC547B or BC107B
- T3 = BC141 or BC142
- D1 = DUS
- IC1 = 7413

**Miscellaneous:**
- Relay 5 V-8 V coil 68 Ω or greater, see text, normally open contact rated to suit current taken by projector remote control.
MAGNETIC-FIELD SENSORS

Announced as being more sensitive than Hall-effect elements, magnetoresistive sensors (MRS) have recently been introduced by leading manufacturers of electronic components. This introductory article examines their fundamental characteristics and possible applications.

The physical operation of magnetic sensitive resistors is based on the Gauss-effect, which may be summarized as follows: a magnetic field with lines of force perpendicular to a current carrying conductor forces charge carriers to travel along the surface of that conductor; the magnetic field 'pushes' the current into a thin layer, which results in a diminished cross-sectional area for the current to pass along, or, in other words, an increased resistivity of the conductive material. Figure 1 illustrates this effect which has been known for quite some time, but has re-

Fig. 1 The magnet pushes the electric current out of the area with maximum magnetic field strength

Fig. 2 A sufficiently high total resistance can only be obtained by means of a long conductor path.

Fig. 3 Gold stripes have been applied to the resistor track, which make it look like a barber's pole.

Fig. 4 The four resistive elements in a Wheatstone bridge configuration.
mainly disregarded by the electronics industry until quite recently, when suitable alloys were developed to put the effect to practical use. The increase in resistivity caused by the Gauss-effect is minimal with pure metal conductors, with the exception of bismuth (Bi), which is a so-called diamagnetic metal with poor conductivity. However, certain alloys have been developed which are more sensitive to the presence of a magnetic field.

Siemens, for instance, use a semiconductor with antimony (Sb) based alloys, such as indium antimonid-nickel antimonid (InSb-NiSb). This material has semiconductor properties and may be glued onto a permeron, ferrite, ceramic or plastic substrate. The magnetic sensitive resistor is usually realized in the form of a meander path as shown in the sketch of Fig. 2: this is done to achieve a maximum-length current track within the encapsulation. While Siemens manufacture single, flat type resistive elements, Philips have developed complete Wheatstone bridges in a standard transistor case. These devices are made from a thin permalloy layer on a silic on substrate. Permalloy is a 20% iron, 80% nickel ferromagnetic alloy without semiconductor properties. The resistivity of a polycrystalline alloy such as permalloy varies in direct proportion to the angle between magnetic field lines and the direction of the current in the conductor. In order to obtain a maximum operational linearity for these devices, Philips have come up with a special arrangement for the permalloy track; a regular pattern of gold stripes is applied onto the conductive track, at an angle of 45° with respect to the current flow direction. For reasons made clear by Fig. 3, this layout is referred to as a ‘barber’s pole’. Since gold has a much higher conductivity than permalloy, the gold stripes effect a net current turn of 45° with respect to the conductor axis, this causes the current to travel zigzag through the flat conductive track.

A complete sensor device of this type contains two resistive elements that feature an increase in resistance with an increase in magnetic field strength, and another two elements with precisely the inverse property: their resistance decreases in a stronger magnetic field. These four resistors have been connected in a Wheatstone bridge setup, with the same resistor types arranged diagonally, as illustrated by Fig. 4. The diagonal configuration offers a high element sensitivity while minimizing bridge unbalancing by changes in ambient temperature.

One of the most important advantages of magnetic sensitive resistors is their ease of device sensitivity definition by means of the manufacturing process. The new Philips magnetic sensitive Wheatstone bridge devices come in a TO92 style case with four leads: two for the bridge supply voltage and two for the bridge output voltage. Applications are found in any electronic field involving magnetic force detection or measurement. A revolution counter, for instance, may be constructed by mounting a MRS device between a permanent magnet and a cogwheel, driven by the engine; every passing cog will unbalance the Wheatstone bridge and cause an output voltage which may be applied to equipment for further signal processing. Similarly, these devices may be used to determine the angular position of a spindle. If placed close to a current carrying conductor, a magnetic sensor may even perform the function of current transformer.
Sound effects are always popular. One of the most popular effects for 'livening up' disco shows, films, etc., is the (police) siren. The crime series on TV have taught practically everybody the difference between the European two-tone siren and the banshee wail of the American version. The circuit described here can produce either sound.

The basic principle of the siren is shown in the block diagram (figure 1).

The first section is an oscillator (Astable Multivibrator, or AMV). For the European siren, the square-wave output from this oscillator is fed direct to the control input of a Voltage Controlled Oscillator (VCO). This causes the VCO to switch to and fro between two frequencies.

For the American siren, the output from the AMV is first passed through an integrating low-pass filter. The output from this stage is something midway between a saw wave and a triangular wave. When the VCO is driven by this signal, the result is a close approximation to the noise made by the American cops.

The complete circuit is shown in figure 2. Transistors T1 and T2 are the active elements in the AMV. With S1 in position 'E' (for European) the time-determining elements are P1, R2, R3 and C2. P1 sets the 'switching frequency'. The time-determining elements for the American siren are P2, R3 and C2. P2 sets the 'wailing speed'. Any number of additional preset potentiometers can be added if further siren effects are required.

The main components of the integrator are P3, R10, C5 and T3. P3 sets the amplitude of the output signal from this stage, so it is used to set the difference between the highest and lowest frequency of the American siren.

Transistors T4...T7 are the active elements in the VCO. The voltage at the control input (base of T6) determines the output frequency. For the American siren, the control voltage is the output from the integrator. Since this voltage swings up and down in the rhythm of the AMV, the output from the VCO will swing up and down in the same rhythm.

The centre frequency of this wailing siren is set with P6.

For the European siren, the square-wave output from the AMV is fed direct to the VCO, causing the latter to produce two frequencies alternately. P5 sets the lower of the two, and P4 sets the difference between them — so it can be used to set the higher frequency.

The adjustment procedures for the two sirens are quite simple.

For the European siren, first set the desired switching frequency with P1. Then set the lower frequency with P5; finally, set the upper frequency with P4. The siren is slightly more difficult to adjust. First set the 'wail speed' with P2. Then adjust P5 and P6 to get the desired effect. Note that P3 will need readjustment if the setting of P2 is altered.

If more than one American siren is to be preset, an extra switch will be required between C3 and P3, so it becomes possible to switch in several different presets for P3.

Alternatively, normal potentiometers can be used with a calibrated scale. An almost infinite number of different siren settings can then be 'dialed in'.

Figure 1. Block diagram of the siren.

Figure 2. Circuit diagram of the complete unit. The three switches can be coupled for ease of switching between the American and European type of siren.

Figure 3. Printed circuit board and component layout.
EARLY DETECTION OF ELECTRONIC FAILURES

by H.A. Cole, CEng, MIERE

The graphical relationship between the failure rate and operating time of virtually any man-made product follows a curve which, because of its shape, is known as a "bathtub" curve. Such a curve has three distinctive regions, the first of which represents an unexpectedly high failure rate within the first year of operation. The central flat region, extending from about one to ten years, represents normal operating performance where the failure rate is as predicted. The third region represents the so-called "wear out" phase where an increasingly high failure rate is to be expected as the product enters its end of useful life period. Failures that occur in the first year of operation fall into three categories:

- Failure to function on the very first occasion (dead on arrival).
- Failure almost immediately after first use (instant mortality).
- Failure early in the first year of use (early life failures).

Those in the first category should, ideally, never be experienced by the end user since they ought to have been discovered by the retailer before the product was delivered. Such faults are usually simple to rectify. The second category failures are almost always experienced by the end user, usually within a few days, hours or weeks, depending on the length of continuous operation and working environment experienced by the product. It is this type of fault that causes the greatest annoyance to users and the most damage to the reputation of retailers and manufacturers.

Reputation under threat

Failures that fall into the third category, although less of a shock to users, are nevertheless likely to result in feelings of disappointment and resentment at being let down. Such failures also represent an additional cost to the manufacturer in honouring product guarantee agreements. All premature failures are bad for the reputation of a manufacturer since customers who feel they have been let down tend to have long memories of brand names and are only too pleased to pass on their unpleasant experiences to other potential customers. It is therefore, in the interests of everyone, for the manufacturer to do everything reasonably to weed out products that are likely to fail prematurely. One of the simplest ways of weeding out a potentially faulty electronic product is to operate the finished version or its sub-assemblies at an elevated temperature for a given period of time. Doing this speeds up the early failure rate, shortening the time period of the start of the bathtub curve and quickly identifies those products or components that would otherwise have failed within the first year of normal operation. The technique of doing this sort of test is known as "burn-in", the purpose of which is to ensure that the finished product begins its normal operating life at the start of the flat central region of the bathtub curve. A particularly attractive feature about burn-in is that it reduces the needs for a large inventory of expensive test equipment as well as time consuming test procedures on virtually every component.

Early failures

In practice, the magnitude of the elevated temperature is limited by the design rating of the individual parts and components of the product. Semiconductor devices such as integrated circuits are usually burn-in separate from other components at a temperature of 125°C for periods of up to nearly 170 hours. Experience has shown that over 80 per cent of all likely early failures in semiconductor devices show up during the first 24 hours of burn-in at 125°C and also that for every 10°C rise in operating temperature the burn-in time could be halved. Fully assembled printed circuit boards are limited to temperatures of about 70°C. They consequently require longer burn-in times to achieve the same results that would have been achieved had the burn-in temperature been much higher. Even lower burn-in temperatures are permissible on fully assembled products. The simplest and least expensive method of burn-in is undertaken under static operating conditions where the component or product under test is placed in a temperature controlled oven and subjected to the required burn-in temperature. Unfortunately, not all faults manifested their presence under such passive operating conditions. A more reliable form of testing is by dynamic burn-in, where the components are continually subjected to the sort of electrical stresses and power handling excursions likely to be experienced under normal operating conditions. Dynamic burn-in may be extended to include monitoring of the performance of individual components under test. Clearly dynamic burn-in systems call for a larger quantity of ancillary test equipment and a more sophisticated monitoring programme than is the case for static burn-in.

Trans-global deal

An excellent example of modern dynamic burn-in equipment is that manufactured and marketed by Sharetree, one of Britain's leading manufacturers of stress testing equipment for the semiconductor industry. This company has recently concluded negotiations with Trio Tech International in Singapore for the joint manufacture of an advanced range of computer controlled burn-in systems.

Under the agreement, Sharetree will supply electronic sub-assemblies which will be built into completed systems by Trio Tech's manufacturing plant. Design work has been completed and the first kit was shipped to Singapore in July 1986. In the Sharetree burn-in system the device under
The monitor card is used when the user wishes to compare the dynamic performance of the DUT with that of a reference device, known to be of faultless performance, that is mounted on the program card. Any discrepancy between the two devices is readily identified and recorded by an associated microprocessor data logging facility.

The Sharetree system provides the user with a range of options that should meet the majority of varying requirements. At one extreme there is a parallel bus system that allows maximum packing density of DUTs per board, up to 225 16-pin integrated circuits. At the other extreme a fully flexible facility allows the programming of various device types on a single card at the expense of packing density.

An important advantage of the fully flexible system is that the DUT boards can be made to accept a variety of device types simply by changing the program card. For example, a device board fitted with an array of 16-pin dual inline sockets can be made to accept 8-pin, 14-pin or 16-pin devices. A fully flexible type of DUT board has a maximum packing density of 120 16-pin devices.

Sharetree Ltd, 70 Westward Road, Stroud, Gloucestershire GL5 4JA.

**A MILLION FRAMES HOLD THE NEW DOMESDAY**

by Amanda Wood

Armchair exploration of every square kilometre of Britain, by directing the display on a video screen, will be possible from November 1986, when the BBC’s electronic Domesday project is completed. The information input is based on work begun in November 1984 by 14,000 schools and local organizations, as well as national bodies. Their combined data are in the process of being transferred to two optical video discs resembling long-playing records, which will display more than a million picture and text colour frames—depending on method of classifying screen displays. The discs will be played on a laser disc player working in tandem with a microcomputer and screen.

BBC Enterprises plans to sell the discs to schools, business houses, libraries, universities, tourist authorities, and anyone who wants to see what Britain looks like 900 years after the first detailed record of 1086.

The original Domesday Book was a survey of England ordered by King William I, in which information on the population and land ownership and use was recorded. The purpose was to give England’s first Norman ruler a record at the extent of Crown lands and to provide a framework for taxation. It provided a picture of life at the time which is unique in Europe.

The original Domesday described every village and field in abbreviated Latin but was largely unread—even by William the Conqueror, who died before its full transcription. The user can start with an aerial satellite picture of the United Kingdom and then, by stages, select from some 23,000 four-by-three kilometre map sections. The user can then go on to text and photographs of structures and daily life in the area, and can even screen ground plans of famous buildings or monuments such as Stonehenge. This can be done simply by pointing a cursor and pressing a hand-held mouse which takes one beyond the subject on the screen, either direct to the next stage or to a printed menu of options.

The user can type in a place name, a subject of interest on a postcode and get a map of the area covered, which can then be researched in greater detail.

The project began with volunteer groups being allocated the 23,000 four-by-three kilometre blocks from the Ordnance Survey. For each block they provided 20 pages of descriptive text about local life, with colour photographs and basic sale figures for every square kilometre, including amenities and land cover—grassland, woodland, housing, or industry. Complementing this Com-
PIONEERING NUCLEAR POWER FOR PEACEFUL PURPOSES

by James Varley, Editor Nuclear Engineering International

When it comes to civil nuclear technology, Britain can claim membership of a very exclusive club indeed. It is one of only four or five countries that have successfully brought to fruition a completely home grown technology for generating electricity from the atom. It can also lay claim to being the first country to build and put into commercial operation a nuclear powered central generating station. This was Calder Hall, which has been supplying electricity since 17 October 1956.

In the British design of reactor, which is used in all the country’s commercial nuclear power stations circulating gas (carbon dioxide) is used to carry heat from the nuclear core to the boilers. As in a conventional coal or oil fired power station, the boilers produce the steam to drive turbines, which in turn drive alternators and produce electricity.

In 1983, some 47 per cent of Britain’s electricity came from reactors of this type which are known as gas-cooled reactors. Most of the remaining electricity was generated from coal.

On the rise

In 1978 the nuclear figure was around 12 per cent—so the contribution from gas-cooled reactors has been steadily increasing in recent years. It is also destined to keep rising in the near future: three large advanced gas-cooled stations, each of 1200 MW, are in the process of being brought up to full power, although, it must be admitted, behind their original timetables. In addition, a further two advanced gas-cooled stations of the same large size are under construction. Primarily as a result of lessons learned from the earlier units, these two massive and complex nuclear construction projects are exactly on schedule. Currently about half completed, they should be in operation in three years’ time. This will bring Britain’s commercial nuclear generating capacity to about 12 000 MW.

About one-third of this will come from the older Magnox units, the early design of gas-cooled reactor. The remainder will...
come from reactors of the later AGR (advanced gas-cooled) design.
In this continuing pursuit of gas-cooled nuclear technology, the United Kingdom has followed an independent path.
Although countries such as Italy, Spain, France, and Japan built one or two gas-cooled reactors in the early stages of their civil nuclear programmes, water-cooled reactors, principally the pressurized water reactor (PWR), which originated in the United States of America as a submarine propulsion unit, have proved more popular with the world's electricity producers.

**Water instead of gas?**

Water-cooled reactors have, in fact, achieved almost complete domination of the world market in the event, despite high hopes of the early days, Britain has only exported two complete nuclear power stations, the Latina Tokai Magna units, to Italy and Japan respectively.
Both of these date back to the late 1950s. Indeed, even Britain itself is now in the process of taking a hard look at the PWR. The country's next proposed nuclear plant, which has been the subject of a public inquiry, the results of which will not be known until the middle of this year, is a PWR known as Sizewell B. If this project succeeds, it could spell the end of gas-cooled reactor construction.

Some people might argue that this would be a great pity in view of the massive investments made in modern plant and production techniques for the latest AGRs. These new techniques include the use by Northern Engineering Industries (NEI) Nuclear Systems of a unique computerized robotic welding system in the manufacture of boilers. But with the country's many years of experience in manufacturing to the stringent standards demanded for nuclear power stations, British companies rightly argue that they are well equipped to make a substantial contribution to nuclear power plants of any kind—gas-cooled or otherwise.

**If Sizewell is approved**

The £1000 million Sizewell B PWR would give them a chance to prove this. Although it would use the technology of the United States company Westinghouse, over 90 per cent of the work would go to British firms. Letters of intent, subject to the project going ahead, have already been received by a boilermaking firm, Babcock Power (which has recently carried out a major investment programme at its works in Scotland) and NEI Nuclear Systems.
These letters are for the steam generators (which is nuclear jargon for boilers) and the pressurizer. These are some of the very demanding large components needed for the primary circuit, the giant piece of very high integrity plumbing which circulates water through the core and the steam generators.

The US/UK nuclear joint venture is hoped to be in production by 1986.

**Nuclear exports**

Among the most prominent of British companies in overseas nuclear projects has been GEC, which joined Westinghouse to build South Korea's first nuclear station. The British designed and built major parts of the nuclear section of the plant and all of the "unconventional" side (turbines, alternators, etc.), as well as sending turbo-machinery to other South Korean nuclear stations. GEC has supplied turbine generators to plants in Canada, Sweden, India, and the United States.

NEI Parsons is another prominent exporter of turbo-machinery for nuclear plant, having supplied South Korea as well as many Canadian nuclear reactors, all of the Candu type. The latter units have some of the world's best performance records, and NEI Parsons is currently working with Atomic Energy of Canada (the Candu vendor) on a possible Turkish plant.

As well as turbine generators, British firms have supplied a large range of smaller components to nuclear power stations around the world. These have included valves, pumps, pipework, insulation and pressure vessels, and the customers over the years have covered the whole gamut of reactor types.

**Reprocessing of fuel**

One of the most consistently successful export businesses for the United Kingdom nuclear industry has involved the uranium fuel on which nuclear power stations run. British Nuclear Fuels Ltd (BNFL), employing around 45 000 people, is one of the world's largest nuclear fuel companies and provides extensive services for export markets, including mainland Europe, Japan, and North America. Among its activities are fuel manufacture (including the highly sophisticated technology of uranium enrichment) for all types of reactor and recycling or reprocessing of used fuel. BNFL is currently involved in a £300 million refurbishment programme which should ensure it remains in the forefront of the high technology nuclear fuel business.

Another area where Britain's nuclear industry is likely to play an increasingly important role is in the development of the fast breeder reactor, an advanced type that effectively breeds its own fuel. Although it is unlikely to have any commercial application before early next century, recently signed agreements will ensure that the United Kingdom plays a key role in the large European demonstration fast reactor plants that will need to be built in preparation for commercialization. All this means British industry will continue to take a pioneering role in the development of peaceful uses for nuclear technology, as it has in the past.

(LPS)
A series of liquid displays—LCDs—available from Sharp Electronics offers models which can display up to 4 lines each with from 6 to 80 characters. Some versions have an integral character generator, in a few cases complemented by a controller. This article will concentrate on the Type LM16251, which has an integral character generator and controller, and needs only two supply voltages. The LM16251 has a viewing area of two lines, each of which can accommodate up to sixteen characters. Characters are normally displayed on the upper line, and the lower line is then used for a cursor. The display is soldered onto a PCB containing the backup electronics, which is CMOS and TTL compatible. Typical current consumption is of the order of 7 mW. There is ample diode protection and the whole unit is easily connected to a four- or eight-bit microprocessor system.

Dimensions are: PCB 84x44 mm; LCD housing 70.5x34.2 mm; viewing area 56.7x11.5 mm; character with cursor 5.55x2.95 mm.

Facilities
A total of 192 characters is available from the character generator as shown in Table 1. These comprise:

- 00-07: 8 characters to be defined by the user;
- 20-7F: 96 ASCII characters;
- A0-DF: 64 Japanese characters (kanji);
- E0-FF: 32 special characters, such as Greek letters and lower case letters with descendents.

Apart from the 192 characters, the unit processes other instructions as well, for instance: erasure of displayed characters; positioning of the cursors; on and off switching of the cursors; shifting of characters on the display; and others. The characters...

Table 2. Instructions and corresponding actions.

Fig. 1. Circuit diagram of a possible set-up.

always appear in the cursor position, irrespective of whether the cursor has been switched on or not. Collective data and addresses of cursor positions may also be displayed. Moreover, it is possible to determine the busy flag whether the unit has executed the previous command and is ready for the next instruction. The addresses in Table 2 apply only to an unshifted display. With each shift (SC=1 or SC=0), the addresses are also displaced, so that position upper left can no longer be selected with address 00. It is, therefore, advisable initially to work without shifting the display (SC=0 and SC=0) and leaving the cursor switched on (C=1). Writing data as well as programming the character generator also shifts the cursor (but not the addresses), so that these must be relocated by appropriate commands after the stated operations have been completed.

With BF=1 (busy flag), the device is executing a command; when BF=0, the circuit is waiting the next instruction. If an attempt is made to write data or instructions when BF=1, overheating at both ICs may result.

Circuit example

A possible circuit is shown in Fig. 1, which uses a Z80A; the memories and other peripherals have been omitted for simplicity’s sake. The Z80A is suggested, because this can readily be synchronized with the relatively slow display via its WAIT input.

Address decoder Type 4028 is connected to IORQ, and only to WR or RD, to facilitate writing as well as reading of the LCD with the least possible number of components. In case outputs Q₂, Q₃ of the 4028 are used for the control of further IO functions, it is necessary to select a number of addresses for the write and read functions.

been completed.

The signal at Q₀ of the 4028 is used to switch on monostable Type 4528. The internal delays in the decoder and the monostable amount to some 140 ns. Network R₋Cₛ stretches the pulse at the Q₀ output of the 4528 to about 700 ns. These times ensure that a machine-language programme can load the display so that the thirty-two characters appear simultaneously (at least as far as the human eye is concerned).

The inverted pulse at the Q₀ output of the 4528 is led to the Z80A to ensure that the data and the WR controlled level at the R/W input of the LCD remain stable for a sufficiently long time. This momentary stopping of the microprocessor does not affect the operation of the dynamic RAM.

The clock (e) output of the Z80A is converted by OR=0, D₋Cₛ to a negative voltage, which is set to about −2 V by R₁. The precise value can only be set during actual operation. The circuit operates well with a clock frequency up to 4 MHz. If the slower 4514 is used as address decoder, the clock frequency should not exceed 2 MHz.

Some practical hints

When the LCD is switched on, the upper line should become dark, whereas the lower one should remain bright. If this does not happen, Vₛ must be made more negative until it does.

Next, the first instruction may be given to the LCD. At all times the busy flag should be consulted (read the address and link it via an AND gate to 80). The very first instruction should be to initialize the LCD by switching RS to 0 and feeding DL=1, N=1, i.e. 3Bhex, to the display. The upper row should now also light. From now on the sequence of commands is arbitrary. For instance, to switch the cursor on, feed 01 into the LCD (which quenches the display), then D₋1, C₋1, and B=Q, i.e. 3Bhex. Since the cursor should function on a monitor screen, also feed 0Bhex into the LCD, as well as ID=1 and S=0. The LCD is now ready for the first character. Switch RS to 1 and feed in succession 31hex, 32hex, and 33hex into the LCD, when figures 1, 2, and 3 should be displayed. If not, Vₛ is not negative enough.
This is the moment to set $V_S$ correctly with the aid of the small preset at the back of the LCD board. The setting will depend to some extent on the angle at which the display will be viewed.

The cursor can then be set at the centre of the lower row, i.e., at address 48, by writing $C8_{\text{hex}}$ after $RS$ has been made 0. Next, the user-defined character can be placed here by setting $RS$ to 1 and writing $Q3_{\text{hex}}$ into the display. The line 1 of this character is programmed by setting $RS$ to 0 and writing $D1_{\text{hex}}$ character $01_{\text{hex}}$ line $001_{\text{hex}}=59_{\text{hex}}$ into the display. The line should then consist of three dots. Then set $RS$ to 1 and write $0010_{\text{hex}}=15_{\text{hex}}$ into the display.

To shift the three digits and the other character to the right, set $RS$ to 0, SC to 1, RL to 1, and write $1C_{\text{hex}}$ into the display. That the addresses have also shifted to the right can be seen by setting the cursor to address 00, i.e., writing $80_{\text{hex}}$ into the display; the cursor will then appear underneath figure 1. The characters are returned to their original position by writing the instruction home, i.e., $02_{\text{hex}}$.

### Table 3. Pin connections

### Table 4. Summary of instructions

$x$ = arbitrary
Control amplifier

Transistors T1 and T2 form a voltage amplifier with a high input impedance and a low output impedance. When the slider of preset potentiometer P1 is set to give the full value of 1 k, the input sensitivity in combination with the 3-watt amplifier is about 150 mV for the 12-volt version working into a 4-Ω load, or 200 mV for the 17-volt version working into an 8-Ω load.

If a higher input sensitivity is required, P1 can be set to a value lower than 1 k. If switching to different values of input sensitivity is needed, fixed resistors can be used in place of P1, with values determined according to the formula:

$$R_x = \frac{500 \times V_{in}}{300 \times V_{in}}$$ (ohms)

where $V_{in}$ is the RMS input voltage in mV. The formula holds good for input voltages from 5 mV to 250 mV. T3 is used in a standard Baxandall tone control circuit. The 1 n capacitor between the collector and earth is to prevent oscillation.

AUSTEREVO

Here is an interesting project for the audio enthusiast, who likes to play around with the circuit rather than just assemble a given project. The ‘Austereo’ has been split up into modules which can be combined to build a stereo amplifier of your own choice, or you can use any of the modules in a design of your own!
Disc preamplifier

The disc preamplifier, of which only one channel is shown in the circuit, incorporates equalisation to correct the output of a magnetic cartridge according to the RIAA playback curve, and also amplifies the signal to a level sufficient to drive the control amplifier. It consists of a two-stage voltage amplifier, T4 and T5, with the RIAA feedback network R18, R19, C15 and C16 connected from the collector of T5 to the emitter of T4. DC feedback and biasing of T4 is provided by R15. The disc preamplifier board should preferably be mounted inside the turntable box as otherwise the capacitance of the screened lead between the cartridge and the disc preamplifier can form a resonant circuit with the self-inductance of the cartridge. If this resonance lies within the audio spectrum it may cause a peak in the frequency response. Of course some cartridge manufacturers quote a recommended load capacitance and if this is so their recommendations should be adhered to. Another good reason for mounting the disc preamplifier inside the turntable is to keep it away from the hum fields of the amplifier’s mains transformer. Turntable motors usually have much less stray field then the average mains transformer! It can be seen that the layout for the two channels is symmetrical.

Resistors:
R1 = 2.4k
R2 = 4M7

3-Watt output

Transistors T1 and T2 form a direct-coupled voltage amplifier. Resistor R6 and diodes D1/D2 determine the quiescent current of the quasi-complementary driver stage T3/T4 and the output stage T5/T6. The values of resistors R7 and R8 are chosen so that the output transistors are either just biased on or just cut off depending on the gain of the transistors used. C3, C5, C6 and R3 help to maintain stability. The input sensitivity of the amplifier is about 400 mV for 12-volt operation with a 4-Ω load, and 600 mV for 17-volt operation with an 8-Ω load. The gain may be increased by reducing R4 but this is not recommended as instability may occur and distortion is increased.

The following layout precautions should be noted when assembling the completed board onto a chassis:

1. Loudspeaker common must be connected directly to the power supply common and should be kept well away from the boards.
2. Separate leads must be run from the supply to the supply points on each board.
3. Outputs of any board should be kept well away from inputs of other boards (except of course where the output of a stage is connected to the input of the succeeding stage).
4. Care should be taken to avoid earth loops. Each section of the amplifier should have only one connection to supply common.

15-30 Watt output

The 'austereo' 3-watt amplifier is used as a drive amplifier for the 2N3055 output transistors, and very few changes in the circuit or the component values are needed. Capacitor C7 is introduced to compensate for the phase shift due to the output transistors. The value of R1 is reduced to 56 k, and additional decoupling, in the form of a 47-k resistor and a 10-pF capacitor, is inserted between the high-potential end of R1 and supply positive. The output impedance is very low, as T5/T7 and T6/T8 form power darlington pairs. The 'austereo' control amplifier is well capable of supplying the 1-V RMS input voltage needed.

Because of the low input sensitivity, the amplifier has good stability and its sensitivity to hum is low. Substantial negative feedback via R4 and R5 ensures low distortion. Maximum permissible supply voltage is 42 V. The power supply circuit is developed from the stabilised power supply unit for the 'austereo' amplifier, with circuit modifications and also changes of component ratings to suit the higher working voltages.

In addition to the heat sinks shown in the amplifier and power supply circuits, the three 2N3055 transistors should be cooled by mounting them on the amplifier or power supply boxes (as applicable) using mica insulating washers. The power supply table is worked out for stereo. Power for the control amplifier is drawn from a 2N1613 with its base potential held at half the main supply voltage.

In this chapter of Digi Course, we introduce another important concept of the logic circuits — the time dependant operation. In case of such circuits which will be described in this chapter, the logic state of the circuits depends not only on the input levels, but also on the moment of time of viewing.

For experimenting with time dependant circuit we shall need some passive components:

- 3 Resistors 3.3 KΩ / 1/2 Watt
- 3 Electrolytic Capacitors 47 µF / 16V
- 1 Electrolytic Capacitor 4.7 µF / 16V

A connecting link will have to be soldered to each lead of these components so that they can be used directly on our Digilex PCB.

The circuit shown in figure 1 is a simple 'Monoflop'

![Circuit diagram](image)

The solid black bar in the capacitor symbol is the negative terminal of the capacitor. Connect this terminal to zero level (ground line) so that the capacitor is fully discharged. The capacitor voltage is 0 V and the output indicator LED lights up because of the NAND gate inverter. Now if the "1" or +5V level is given at the negative terminal of the capacitor the LED is turned off for some time and then it lights again on its own.

With a high input to the capacitor, the voltage at the input of the NAND inverter also jumps to "1", thus turning off the LED. As the capacitor slowly charges, the current flow through 3.3K resistor decays and along with that the voltage at the input of the NAND inverter also decays to "0". Once this stage is reached, the output of the NAND inverter again becomes "1" and the LED glows. The time taken by the capacitor to charge is decided by the values of R and C, which also decide the time for which the LED remains turned off.

The circuit in figure 1 can be further modified as shown in figure 2.

With this modification the circuit becomes a controlled Monoflop. With M4 at "0" level the circuit can be disabled and with M4 at "1" the circuit is enabled and becomes operative. Terminal M5 is the trigger input. Many standard ICs have an input similar to the terminal M4 which is called the Enable Input.

The Monoflop just described is also known as a Monostable Multivibrator. The Flipflop described in previous chapters is known as a bistable multivibrator.

Now let us see the effect of connecting two Monoflops in series as shown in figure 3.

When capacitor is switched from "0" to "1" first the LED B is turned off, then after a period decided by the values of R1 and C1, it glows again. At this exact moment of time the second Monoflop gets a transition from "0" to "1" at the input of capacitor C5 which turns off LED A for an equal amount of time, then it glows again.

Similar to the "0" to "1" transition available at M6 when B started glowing again we also have a "0" to "1" transition available at M3 when A starts glowing again. This transition can be further used to trigger the first Monoflop again. Connect the circuit as shown in figure 4 and observe what happens!
The circuit will switch both the Monoflops alternate and the LEDs will glow and extinguish alternately. This is an oscillator — called Astable Multivibrator. The period of oscillations will be decided by the individual values of R1, C1 and R2, C2.

To study the effect of R and C values, change the capacitor C1 from 47 µF to 4.7 µF. Now the period of LEDs A and B glowing and extinguishing becomes unequal. The exact effect is illustrated in the pulse diagram of figure 6. The diagrams on the left correspond to circuit values in figure 3 and the diagrams on the right correspond to circuit values in figure 5.

In engineering language this is called a symmetric and asymmetric duty cycle. A simple explanation of the three terms we have encountered so far in multivibrators is as follows. A Monostable Multivibrator is one which has only one stable state; if we force it to change the state, it returns to its stable state after a fixed period of time. Other names for this circuit are Monoflop or Monoshot.

A Bistable Multivibrator has two stable states, if we force it to change its present state it goes to the other stable state and remains in that state till forced again to change state. Another name for this circuit is Flipflop.

An Astable Multivibrator has two states, but it can never remain in one state permanently. It keeps on changing the states periodically. There is no other name for this circuit.

We can also add one more Monoflop to our Astable Multivibrator to obtain the circuit shown in figure 7.

This circuit gives a running light effect, as the three LEDs turn ON and OFF serially. If this circuit does not start up on its own, it must be externally triggered. Any number of extra Monoflops can be added to this circuit provided that the total number is odd.

In Digital Technology, there are many more oscillator circuits. To anumarata those will be outside the scope of this series. An important point worth mentioning here is about the high frequency oscillators. Such circuits are used for generating the clock frequencies for computers and other applications, and to obtain a stable frequency quartz crystals are used.

The simple oscillator circuit of figure 4 can be combined with one of the counter or shift register circuits described earlier. One such arrangement is shown in figure 8.

Like the Flipflops studied in previous chapters, Monoflops are also available commercially as integrated circuits. One such IC is the 74123 which contains two Monoflops. The Monoflops are retriggerable, that is, they can be triggered again during the ON period. The time period is calculated as follows:

\[ t = 0.32 \times C \times (R + 700) \]

for \( R = 5 \) to 25 KΩ and \( C = 10 \) pF.

In case of electrolytic capacitors, a diode 1N4148 must be used as shown in figure 9, and the period is shortened to

\[ t = 0.28 \times C \times (R + 700) \]

The Monoflops trigger on rising edge at B if A is on “0” and on falling edge at A if B is on “1”.

---

This circuit will switch both the Monoflops alternately and the LEDs will glow and extinguish alternately. This is an oscillator — called Astable Multivibrator. The period of oscillations will be decided by the individual values of R1, C1 and R2, C2.

To study the effect of R and C values, change the capacitor C1 from 47 µF to 4.7 µF. Now the periods of LEDs A and B glowing and extinguishing become unequal. The exact effect is illustrated in the pulse diagram of figure 6. The diagrams on the left correspond to circuit values in figure 3 and the diagrams on the right correspond to circuit values in figure 5.

In engineering language this is called a symmetric and asymmetric duty cycle. A simple explanation of the three terms we have encountered so far in multivibrators is as follows. A Monostable Multivibrator is one which has only one stable state; if we force it to change the state, it returns to its stable state after a fixed period of time. The Monoflops trigger on rising edge at B if A is on “0” and on falling edge at A if B is on “1”.

---
The Oscilloscope

The instrument mostly found in the centre of laboratory work bench is an oscilloscope. The electronics expert finds it the most important measuring instrument. Meaning of the Greek word 'Oscilloscope' translated into simple English would be something like this, "An apparatus for making the oscillations visible". It records the waveforms and displays them on the screen so that they can be visualised as a time versus voltage graph.

Figure 2 shows an oscilloscope with a rectangular waveform being displayed on the screen. The most important data of the oscillations like the voltage values (in vertical direction) and period (in horizontal direction) can be measured directly from the screen. From the screen we can further observe that the edges of the waveform are not quite sharp as would be expected in an ideal rectangular waveform.

The Structure:
The main part of the oscilloscope is obviously the screen - which is the front face of the picture tube or the Cathode Ray Tube (CRT). The shape of the CRT can be seen in figure 4. The front face is coated with a Phosphorous layer on the inside, and this forms the screen where waveforms are displayed. The CRT has a vacuum inside it. An "Electron Gun" is situated in the neck portion of the CRT, which "shoots" Electrons onto the front screen. When the beam of electrons hits the phosphorous material on the screen it creates a glowing dot on the screen due to the energy being carried by the electron beam.
Two deflecting plate pairs are used to deflect the electron beam in the desired direction. By applying a voltage to the deflecting plates, the deflection is achieved towards the plate which is more positive. As the deflecting force acts both in horizontal and vertical direction, the resulting force can take the beam and the glowing dot to any position on the screen.

The vertical pair of plates deflects the beam horizontally and the horizontal pair of plates deflects the beam vertically. The vertical pair is called X-plates or X-deflection plates and the horizontal pair is called Y-plates or vertical deflection plates.

The X-plates are normally fed with a saw-tooth voltage. (Figure 5) This voltage deflects the beam periodically from left to right and back on the screen, generating a steady horizontal glowing line on the screen. The return is very quick and the beam is blanked during the return, so that we see only the left to right trace on the screen. The waveform to be measured is applied to the
Y-plates. This superimposes the vertical movement on the beam, which is directly proportion to the voltage on the Y-plates. Thus what we see on the screen is a graph which shows the time on X-axis and voltage on Y-axis, giving the true picture of the waveform being measured. The scanned image remains visible on the screen only for a fraction of a second. However the sawtooth on X-plates makes it repeat continuously, and the glowing image is refreshed on every cycle of the sawtooth wave. In order that the image formed in each cycle of the sawtooth perfectly coincides with the image formed in the previous cycle, a special device is used to trigger the sawtooth exactly on the same point in the waveform being displayed. This gives a steady image on the screen. To simplify what happens during the trigger operation we can visualise that the trigger circuit makes the glowing dot to wait on the left edge of the screen till the input waveform reaches a particular voltage level which is set as the trigger level. When it reaches that level, the sawtooth sweeps one cycle across the screen. In addition to the triggering device, it is also essential to have a control over the period of the sawtooth, so that the time scale on the X-axis is under our control. If the frequency of sawtooth is very high, the screen shows only a small portion of the input waveform. If the frequency of the sawtooth is very low, the screen will contain many cycles of the input waveform.

The Function:
A block schematic diagram of the oscilloscope circuit is shown in figure 6. It clearly shows all the functional blocks we discussed so far. The cathode K is heated by the heater coil H to such an extent that it starts emitting electrons. This process can be compared with boiling water which emits water molecules from the surface in form of steam. As soon as the electrons leave the cathode plate and enter the vacuum they are attracted and accelerated end focused by the electrodes A1, A2 and A3. As the electrodes are circular and open in the center, they do not absorb the electrons but allow them to pass through at an accelerated speed in form of a bunch in the direction of the screen. This bunch of electrons moving at an accelerated speed forms a sharp beam which finally hits the phosphorus layer on the screen. There is also a cylindrical electrode in between the cathode and anodes which has an adjustable negative voltage on it. This voltage decides the amount of electrons that will finally reach the screen, by deflecting back the remaining electrons towards the cathode again. This voltage is called the Wehnelt Voltage or Z-Voltage, and regulates the flow of electrons. It also carries out another important task. When the beam jumps back from right to left, a strong negative pulse is given to the Z-electrode (Wehnelt Cylinders) so that the return of the beam is not seen on the screen.

Figure 6:
The block schematic diagram of the oscilloscope circuit.
As the electron beam travels at a high speed, both the X and Y deflection voltages must be sufficiently high to be able to deflect the beam. To raise the voltage level for the deflection plates, two amplifiers called X-Amplifier and Y-Amplifier are used. The X-Amplifier is fed from the saw-tooth generator and the Y-Amplifier is fed from the input signal. The Y-Amplifier is very sensitive and can process very low input voltages. If the input voltages are quite high, it is attenuated with voltage dividers before feeding it to the Y-Amplifier.

There is one more anode on the CRT on the wall of the tube which is supplied with a very high positive voltage between 2 to 15 KV. This further accelerates the electron beam and gives them a very high energy which is converted into light when the beam hits the phosphorous layer on the screen. After delivering the energy to the screen, the slowed down electrons are absorbed by the high voltage anode and complete the circuit.

Front Panel Controls

Every oscilloscope will have a different type of front panel layout, and the nature of controls available will depend on the type of oscilloscope and the level of sophistication. Controls on a simple single channel oscilloscope are described here with the help of a typical front panel shown in figure 7. Some oscilloscopes are equipped with two input channels and can display two waveforms simultaneously on the screen for mutual comparison. Typically the input and output waveforms of an electronic circuit can be studied in relation to each other with the help of this function. Such oscilloscopes have two independent Y-Amplifiers end the trace in generated by the same saw-tooth for both the channels.

An intensity control appears below the screen. This controls the brightness of the display by controlling the Wehnelt Voltage. Focus control is also provided to adjust the sharpness of the beam.

With the switches above the input connector, the method of operation of the oscilloscope can be selected:

- **DC**: for direct display of the true input voltage
- **AC**: for display only the AC component of the input voltage
- **CT**: for component test function available in some oscilloscopes
- **GD**: Ground for indicating the zero line

The rotary switch marked Y-Amplifier controls the attenuation of the signal going to the Y-Amplifier. It is calibrated in V/cm or mV/cm. The figures show how many Volts or milli Volts are represented by 1 cm in the vertical direction on the screen. This measurement is enabled by the caliper grid drawn on the screen. The Y-Position knob allows you to move the image up or down on the screen.

The right side of the front panel has the horizontal portion controls. The saw-tooth generator or the time base control is achieved through a rotary switch calibrated in ms/cm or us/cm. Which decides the slope and period of the saw-tooth wave that is fed to the X-Amplifier. The setting of this switch tells you how much time is represented by one centimeter in the horizontal direction on the screen.

Located under this rotary switch are the trigger selection switches. The models of triggering can be selected through these switches. The triggering can be either through the external trigger, by a TV video signal, or by a rising or falling edge. When the "AT/Norm" knob is pressed, the trigger level can be controlled through the "Level" knob. The "Hor. Ext." switch disconnects the X-Amplifier from the saw-tooth generator and connects it to the external horizontal input socket. The X-Position control allows you to move the image left or right. The 'CAL' terminal provides a 1 KHz rectangular wave with a 200 mV level for calibration of the display.

Unfortunately the sophisticated oscilloscopes are very expensive and generally beyond the reach of a hobbyist.

Figure 7
Front panel controls of a single channel oscilloscope
TV Antenna Signal Distributor

Here is a simple circuit which will allow you to use only one antenna between two TV sets.

No, it’s not as simple as connecting two TV sets in parallel to the antenna! Such a connection will reduce the load impedance seen by the antenna to half the value of impedance of each TV set as shown in figure 1. This will introduce a mismatch.

To get over this problem of impedance mismatch, all you need is three resistances and a capacitor.

Figures 2 and 3 show how this circuit is to be constructed.

The circuit diagram is shown in figure 2, and the actual prototype constructed using half of the Selex PCB (size 1) is shown in figure 3. The shield wire sheathings are connected firmly using three copper or bronze strips. These strips are bent with the help of a 6mm drill bit or a stud end a bench vice where the jaw of the vice are opened about 9 to 10 mm wide and the strip is placed over it. The central portion of the strip is bent into a U shape by keeping the broad side of the drill bit or the stud over it and hitting from the top, so that the strip is driven into the gap between the jaws of the vice. Both ends of this bent strip are now bent back with a hammer.

Soldering of components on the Selex PCB is quite simple and can be done as shown in the layout given in the figure 4. R1, C1 and the antenna cable are soldered together.

The functioning of the circuit is as follows:

The 22Ω resistance in series with the connecting cable of the TV sets increases the 60Ω impedance to about 80Ω. Further when these two are connected in parallel, the impedance seen at the junction of R1, R2, R3 is 40Ω. Thus when added to the 22Ω resistance R1, the antenna sees an impedance of approximately 60Ω again matching with the impedance of the antenna cable.

C1 compensates for the inductance. Because impedance of a resistance increases at very high frequencies due to the effective inductance. As the impedance of a capacitor decreases at high frequencies, it compensates for the increase in impedance of resistors.

Figure 1:
Two parallelly connected TV sets give effectively half the impedance and create a mismatch with the antenna.

Figure 2:
Three resistances and one capacitor matches the effective impedance. However, a part of the antenna signal is dissipated as heat in the resistors.
The disadvantage of this simple circuit is that some of the antenna signal is dissipated as heat by the resistors. But this should not create a problem in areas where signal is quite strong. During construction, be careful and keep all connections as short as possible, and make them well conducting. A small plastic box can be used as housing.

For antenna systems with 75 Ω cables, change the 22 Ω resistances to 27 Ω. C1 can remain 2.2 pf.

Component List:
- R1, R2, R3 - 22 Ω or 27 Ω
- C1 - 2.2 pf (Ceramic)
- 3 Copper Strips, Screws etc.
- 1 SELEX PCB (Size 1) cut into half
- 1 Log Strip

Figure 3:
The actual construction of the circuit, using brass clamps
Figure 4:
R1 and C1 are directly soldered with the antenna cable.

Tips for Selex PCB

There's almost nothing that can't be simplified further. It is also true for the Selex PCB. An easy way to assemble a Selex project on a Selex PCB is to paste a copy of the given component layout directly on the PCB and then insert the components directly in position. If you wish to remove the layout after the soldering is done, fix it only with cello tape. There is no effect on the working of the circuit even if you permanently paste the layout in place and don't remove it after soldering.

The Selex PCB is so versatile that it can also be used to make your own layouts for different circuits. In such case whenever it becomes necessary to cut the tracks, you can use a 3 mm drill bit and turn it back and forth in the hole from the track side. This will remove copper around the hole and open the track.
Mini printer for portable/compact equipment

Epson OEM Division's new M-180 series miniature shuttle printers combine high print quality and speed with low power consumption. The new range includes the M-180, M-181, M-182, and M-183 printers. The basic 24-column M-180 provides a print speed of 1.5 lines per second (LPS) and 144 dots per line (DPL). The M-181 will give 30 columns, 1.3 LPS and 180 DPL; the M-182 will give 36 columns, 1.1 LPS and 216 DPL; the M-183 will give 42 columns, 0.9 LPS and 252 DPL. The paper width is the same for all types at 57.5 mm, and power consumption is low at 200 mA (typ) from a 5V supply, which makes battery operation feasible.

The printers can operate in text and graphics mode; a compact control board, the BA-180 and single-chip dedicated controller, the LA-180, are available to simplify interfacing to the range. Ideal for use in handheld terminals, cash registers, calculators and portable data logging systems, the printers measure 91mm x 46.9mm x 15.8mm.

Top class letter quality printer

Star Micronics have recently introduced a new dot matrix printer, the NB-15. Fitted with a 24-pin head, it is capable of producing draft copy at 300 cps and letter quality printouts at 100 cps. In addition to the standard ASCII set with international alternatives in both draft and letter quality, up to two additional font modules may be in use at any one time, giving a remarkable degree of flexibility.

Standard features of the new LB-15 include both tractor and automatic single sheet feed, easily accessible DIP switches and comprehensive front panel controls, full IBM character set including standard block graphic characters, 16 Kbyte buffer, and easily interchangeable interfaces.

Priced at around £950, the LB-15 is claimed to be significantly better equipped than competitive products, since it offers a true letter quality printout as compared with the current near letter quality offered in most cases.

Single-board controller

New from J.P. Designs is the Gimini 2 hand held controller, ideally suited for real-time applications such as lathe control, robotics, etc, where user interaction may be required.

At the heart of the system is a Type 6502 microprocessor operating at 1 MHz, with up to 8 Kbytes of static RAM (2K provided).
**NEW PRODUCTS**

**THERMOSTATS**

PATEL'S offers a range of Thermostats which provide low cost adjustable temperature controls. The stem is comprised in two parts: inside is made of low expanding ALLOY STEEL ROD and the outer shell consists of a high expanding ALLOY TUBING. This differential expansion principle enables advantages such as:

- Withstands large temperature changes without damage.
- Resistance to vibration.
- Simple and full adjustability over range.
- High sensitivity.
- Inherent temperature anticipation.
- Wide operating range.
- Direct response to radiant heat.
- High switching.

The capacity of the Thermostats is 15 Amps at 240 volts, 50 cycles A.C. They can be fixed in any position.

**EXHAUST FAN**

P/S HIND ELECTRIC & ELECTRONICS introduces a Tube Axial Exhaust Fan for equipment cooling purposes. Features include light weight, heavy duty, low power consumption, 230V 50HZ operation single phase.

**CABLE TIES & MOUNTS**

Microsign Products offer a wide line of versatile one piece construction self locking Nylon cable ties of Miniature-Intermediate Standard section in releasable & Non-releasable type which can secure cables, wires, tubes & hoses from 2mm to 75mm in diameter. Miniature cable ties make neat work of intricate wiring. Tie mounts available with screw provision. Adhesive backed snap in too.

**FLOWMETERS**

Panametrics has introduced a tube gas flowmeter which transmits simultaneously three 4-20 mA outputs: flow velocity, molecular weight, and mass flow rate. These outputs help vertical operators find leaks fast in waste draining steam, protect vapour recovery compressor turbines against overheating when vapour molecular weights fall too low and in general improve material balances and conserve energy and money.

**DIGITAL IC TESTER**

RC Digital IC Tester 4024D is a microprocessor based instrument designed to perform automatic functional testing of TTL, RTL, HTL, DTL, CMOS and MOS ICs. Pre-programmed software for about 300 most commonly used ICs is stored in memory with provision to update the programme for another 100 ICs.

Among important functional features are:

- Automatic identification of an IC number.
- Automatic identification of the power pins of IC, audio alarm for fault indication etc.
- Optional features include logic level testing over recommended supply voltage range.
- Convenient print out and provision for testing IC under wide temperature range. It operates on 230V, 50 HZ AC with low power consumption.

**ABL CAPACITORS**

ABL manufactures a wide range of Capacitors, Polypropylene Capacitors to suit various small signal circuit applications.

These Capacitors are manufactured with Plant and Machinery from Japan in association with Hitachi.

The Capacitors are available in 2.5mm, 5mm, 10mm pitches.

**LINE FREQUENCY METER**

Delta Control Engg. Corp. have introduced 3 digit Line Frequency Meter MFC-3 having resolution and accuracy of 0.1 Hz. It has 0.001% accurate crystal controlled time base, frequency range of 40.0 Hz to 65.0 Hz and 5-Second Sampling interval to give steady and better averaged readings. Enclosure is rugged ABS moulded 1/2 DIN size box, requiring a panel cut-out of 92 mm x 46 mm. It uses high grade components mounted on glass-epoxy PCB for reliability.

Note: Some text is not clearly visible due to image quality or layout design.
SINGLE PHASING PREVENTOR
EEC have developed a Single Phasing Preventor which protects motors against danger of single phase, high & low voltage, phase unbalancing, phase reversing etc. The unit is totally solid state and can be used with any HP motor. It is housed in dust & damp proof sheet steel modular enclosure. An Auto/Off/Manual switch and indicating light is provided.

COATING FOR PCB'S
CRC Acryform, is made in India under agreement with CRC chemicals, Europe. It is a fast drying single component conformal coating for application on printed circuit assemblies. It is easy to apply, has a shelf life of 2 years, and is easy to remove if rework becomes necessary. CRC Acryform is dry to touch (air drying) in 20 minutes. CRC Acryform is transparent, so coated components are easily identified. Single components may be replaced by soldering or desoldering directly through the coating. The cured film can be removed using chlorinated solvents such as methylene chloride or trichloroethylene.

CURRENT SOURCE
Kentley has introduced a new Programmable current source model 224 with the following specifications:
- 5mA to 101MA dc Output
- 1Ω output resistance
- 6 Programmable Current ranges
- Auto Increment/ decrement
- Hi/Lo Limit for Auto increment/decrement
- ±1V to ±10V Programmable V-Limit

FLEXIBLE RELEASE CORD
IEC is now marketing a Flexible Cord/Cable Release System which is specially useful for a panel builder who is often confronted with mis-matching between the Relay actuator and the Push button. The standard Cable release systems are made for a few well-known types of Relays, addition of a suitable clamp can make it useful for any type of Relay. This unit withstands more than 1,000,000 mechanical operations and is slaved with superior insulation to prevent thermal and electrical abuses.

CUTTER - STRIPPER
CYCL-O has developed a new cutter-cum-stripper for electrical cables up to 5 mm in diameter. The stripper strips off wire up to 25 mm/1 inch in length.

TACHOMETER
Advani-Oarkkon have added a new Tachometer. Model DTG R-143 O to their range of power control equipment. This version gives minimum deviation from linearity, minimum ripple in the output voltage, close tolerance regulation and better performance at lower speeds. It is tailored to suit application conditions in various industrial applications. It is designed for speed indication and feedback control of DC variable speed drives.

ROTARY SWITCH WITH ADJUSTABLE STOP
TRS-12 'Comtec' TRS-12 is a Rotary switch which is offered in 3 models, First 1 pole 12 positions, Second 2 pole 8 positions and Third 4 pole 3 positions. A stop ring is provided with each switch to enable the user to adjust the 'switch-stop' position to meet his requirements. Each model is available with primed circuit and solder terminals having tingle plating to impart quick solderability. The body is made up of glass filled Nylon ad the contacts are made from brass and phosphor bronze. The switch at present is offered with non-shorting contacts (Break-before-make), having a rating of 350 mA at 110 V Ac/DC, and with contact resistance of 20 milliohms max. The switch is having a minimum mechanical life of 20,000 detent operations. The shaft accepts any knob suitable for 1/4" diameter.
WANTED well experienced Electronics Engineers with experience in design and development of Electronics Testing and Industrial Instrumentation on regular/consultation basis. Kindly contact Post Box 4324, New Delhi 110019

HURRY! One Chip Radio ICs ZN 415 E Rs 62.00, ZN 416 E Rs 78.00 (All inclusive). Send 50% with order (M.O or D.D) to INTELLIGENT ELECTRONICS, 65, SBI Colony, Gogalnagar, Nagpur 440022

CORRECTIONS

Phase-corrected cross-over filter
(January 1986, p.1-30)

The introductory paragraph to formula (6) should read: "where both the low- and high-pass output are attenuated by 6 dB (the so-called half power points)."

Telephone exchange
(January 1986, p.1-54)

Capacitors C21 and C22 are shown the wrong way around on the PCB lay-out in Fig. 3; the circuit diagram in Fig. 2 is correct.

MSX Extensions — 2
(March 1986, p.3-30)

The text in the third column should read: "to MSX signal CS12, CS2 or CS1 in that order."
